1 Introduction to Photosynthesis
Photosynthesis is how plants turn light into chemical energy.
It takes place in the chloroplasts of leaf cells.
Chlorophyll absorbs mostly red and blue light.

2 The Light Reactions

The light reactions happen in the thylakoid membranes.
Water is split and oxygen is released as a by-product.
ATP and NADPH carry energy to the next stage.

3 The Calvin Cycle
The Calvin cycle takes place in the stroma.
The enzyme RuBisCO fixes carbon dioxide.
The cycle produces G3P, which the plant uses to make glucose.
